

Report Of

Full-Stack Feature Development for a Fintech Web Platform

Submitted To

School of Computer Science and Engineering IILM

University, Greater Noida, U.P.

In partial fulfilment of the requirement of degree of

B.Tech CSE

By

Roll Number of Student: CS-23411553

Name of Student: ADIBA QAMAR Batch:

4CSE5

2026-27

CANDIDATE'S DECLARATION

I, Adiba Qamar, do hereby declare that the internship report titled **"Full-Stack Feature Development for a Fintech Web Platform"** has been completed by me to fulfil the requirement for the award of the degree of Bachelor of Technology in CSE. All the references have been quoted and I have not taken as such any material from any other source. I affirm that this report is my own and has not been submitted to any other institute for any degree/diploma requirement, and I shall be solely responsible for any kind of copyright violation in this regard.

Student Name – Adiba Qamar

Roll No. CS-23411553

ACKNOWLEDGEMENT

I am using this opportunity to express my gratitude to everyone who supported me throughout the internship program at Bluestock.in. I am thankful for their guidance, constructive feedback, and encouragement during this work. I sincerely thank Mr. Yash Kale, Project Manager at Bluestock Fintech, and the wider engineering team, for their mentorship and for sharing their insights on full-stack web development practices, which greatly enriched my learning experience.

I also express my gratitude to my parents and mentors for their continued support and blessings.

4.1 INTRODUCTION

Modern fintech platforms depend on robust, well-tested software to deliver reliable, real-time services to their users. Building and maintaining such platforms requires developers to work across the full stack — from user-facing interfaces to backend logic and data storage — while following structured engineering practices such as version control, code review, and iterative testing. The quality of this engineering work has a direct impact on product reliability and user trust, making disciplined, well-reviewed development an essential part of any fintech company's software lifecycle.

This project was undertaken during a two-month internship (1 June 2026 to 1 August 2026) at Bluestock.in, working as a Software Developer Engineer (Full-Stack) Intern, under the guidance of Mr. Yash Kale, Project Manager. The internship focused on developing and enhancing user-facing features on Bluestock's stock-market platform, along with the supporting backend APIs and data-handling logic needed to power them.

The work involved reviewing existing codebase and design conventions, building frontend components for assigned features, developing and testing REST APIs, integrating frontend and backend layers with the platform's database, and participating in code reviews that compared submitted work against the team's engineering standards. This report documents the organization context, problem statement, objectives, scope, tools, workflow architecture, methodology, and outcomes associated with this internship project.

ORGANIZATION PROFILE

The internship was carried out at Bluestock.in, a fintech technology company building a stock-market research and analytics platform for retail investors in India. Bluestock focuses on making market data, company fundamentals, and IPO information more accessible through a web-based platform, combining structured financial data with an easy-to-use interface.

Bluestock builds and maintains its platform through a small, cross-functional engineering team responsible for frontend development, backend APIs, and data pipelines that keep market information up to date. The organisation follows an Agile-style workflow, with tasks assigned in short cycles and regular check-ins between interns and their reporting manager.

During the internship, the organisation provided access to its codebase, development environment, and code-review process required for feature development. The internship strengthened practical skills in full-stack web development, REST API design, Git-based collaboration, and working within an existing, production-grade codebase.

4.3 PROBLEM STATEMENT

As Bluestock's user base grows, the platform's frontend and backend need to evolve continuously to support new features, fix usability gaps, and keep pace with changing data requirements. New features must be built to match the existing design system and coding conventions, integrate cleanly with existing APIs and database schemas, and pass through code review without introducing regressions.

The problem addressed in this project was the design, development, and delivery of assigned features within Bluestock's platform — covering both frontend UI work and backend API support — in a way that met the team's functional requirements, coding standards, and review expectations, while working within the constraints of an existing production codebase.

4.4 PROJECT OBJECTIVES

The primary objective of this internship was to gain hands-on, full-stack development experience by contributing to a live product at Bluestock.in. The specific objectives were as follows:

- To understand Bluestock's existing frontend and backend codebase, coding conventions, and development workflow.
- To design and implement assigned UI components and pages using the platform's frontend framework.
- To build and test REST APIs supporting the assigned features, including request validation and error handling.
- To integrate frontend components with backend APIs and the platform's database.
- To participate in code reviews and incorporate reviewer feedback into subsequent commits.
- To identify and fix bugs surfaced during manual testing and QA cycles.
- To understand how individual feature contributions fit into Bluestock's broader product and release cycle.

4.5 SCOPE OF THE PROJECT

This project is limited to the feature(s) and module(s) assigned through Bluestock.in's internal development workflow during the internship period (1 June 2026 – 1 August 2026). The work covered frontend development, backend API development, and their integration for the assigned modules.

The project includes the following activities:

- Review of the existing codebase, design system, and API conventions used by the team.
- Development of frontend components and pages for the assigned feature(s).
- Development and testing of backend REST APIs supporting those features.
- Integration of frontend and backend layers with the platform's database.
- Participation in code review cycles and resolution of reviewer feedback.
- Manual testing and bug-fixing prior to feature hand-off.

The project does not include production deployment or infrastructure management, architectural redesign of the platform, or work on modules outside those explicitly assigned. The findings and observations are specific to the tasks assigned during this internship and are not claimed to generalise to all projects at the organisation.

4.6 TECHNOLOGIES AND TOOLS USED

This project required tools for frontend and backend development, version control, API testing, and team collaboration. The work was primarily carried out using Bluestock.in's internal codebase, supplemented by standard full-stack development tools.

Category	Tool / Platform	Purpose
Frontend	React.js, HTML5, CSS3, JavaScript (ES6+)	Building UI components and pages
Backend	Node.js, Express.js	REST API development and business logic
Database	MongoDB	Data storage and retrieval
Version control	Git, GitHub	Source code management and collaboration
Project management	Trello, Slack	Task tracking and team communication
Testing / Debugging	Postman, browser DevTools	API testing and debugging
Documentation	MS Word / Google Docs	Internship report and summary preparation

Table 4.6: Technology stack used for the internship project.

4.6 SYSTEM ARCHITECTURE

The development process followed a structured pipeline beginning with task assignment and ending with a reviewed, merged feature. Tasks were assigned through the team's project board, with a short discussion to clarify requirements and expected behaviour before development began.

Each assigned feature was built starting with the frontend component or page, followed by the backend API endpoints needed to support it, and finally the integration between the two using the platform's existing data layer. Once a feature was functionally complete, it was submitted as a pull request for code review, where a senior developer checked it against the team's coding standards and functional requirements. Review comments were addressed through follow-up commits before the feature was merged and handed off for QA.

Overall data flow for a typical feature followed this path: React frontend components → REST API layer (Node.js/Express) → MongoDB database, with responses flowing back up the same path to update the UI.

4.8 METHODOLOGY

4.8.1 Onboarding and Codebase Familiarisation

At the start of the internship, time was spent reviewing the existing frontend and backend codebase, understanding the folder structure, component patterns, and API conventions already in use. This stage also involved setting up the local development environment and getting familiar with the team's Git branching and pull-request workflow.

4.8.2 Feature Development

Assigned features were developed by first building the required UI components in React, matching the platform's existing design patterns, and then implementing the corresponding backend endpoints in Express to handle data validation, processing, and storage in MongoDB. Frontend components were then connected to these APIs, with attention paid to loading states, error handling, and edge cases such as empty or invalid data.

4.8.3 Testing and Debugging

Backend endpoints were tested independently using Postman before frontend integration, checking both expected responses and error conditions. Once integrated, features were manually tested in the browser across common user flows, using browser DevTools to debug rendering issues, failed network requests, and state-management problems.

4.8.4 Code Review and Feedback Loop

Completed work was submitted as pull requests and reviewed by a senior team member against the project's coding standards and functional requirements. Where review comments were raised — most often around code readability, consistent styling, or handling of edge cases — the corresponding changes were made and re-submitted until the pull request was approved and merged.

4.9 EXPECTED OUTCOMES

Metric	Illustrative Observation
Feature area worked on	User-facing dashboard and supporting APIs
Review cycles per pull request	Typically 1–2 rounds of reviewer feedback
Most common review comment	Edge-case handling and code readability
Least common review comment	Security-related concerns
Outcome of feedback loop	Fewer review comments and faster PR approval in later weeks

Table 4.9.1: Illustrative summary of feature-delivery outcomes observed during the internship

Across the internship, most review feedback related to edge-case handling and code readability, while security-related comments occurred less often but were treated with the highest priority whenever raised. This pattern reflects the intuition that day-to-day feature work surfaces mostly usability and consistency issues, while deeper architectural or security concerns are rarer but carry greater weight during review.

Overall, the internship reinforced that disciplined version control, clear API contracts between frontend and backend, and a consistent code-review process are central to delivering reliable features in a production codebase. Structured onboarding and mentorship from the team reduced ramp-up time, and iterative feedback from code review measurably improved the quality and consistency of the code delivered over the course of the internship.
